(57) **ABSTRACT**

A method of joining a first bulk composite core and a second bulk composite core by applying an adhesive to a surface network of the first bulk composite core; inserting a plurality of mandrels into a plurality of cell members of the first bulk composite core and a plurality of cell members of the second composite core, thereby aligning the cell members of the first bulk composite core to the cell members of the second bulk composite core; pressing the respective surface networks of the first bulk composite core and the second bulk composite core together with the adhesive located therebetween; and curing the adhesive.

SYSTEM AND METHOD OF POST-CURE PROCESSING OF COMPOSITE CORE

BACKGROUND

1. Technical Field

The present disclosure relates to a system and method of post-cure processing of bulk composite core.

2. Description of Related Art

Typically, composite core is built in a large bulk shape that must be cut into usable slices that can then be milled to a final shape. Conventionally, cutting bulk composite core can be a labor intensive operation and result in a large amount of waste. Further, certain shapes of bulk composite core tend to distort during the cutting process.

Hence, there is a need for an improved system and method of post-cure processing of a bulk composite core.

DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the system and method of the present disclosure are set forth in the appended claims. However, the system and method itself, as well as a preferred mode of use, and further objectives and advantages thereof, will best be understood by reference to the following detailed description when read in conjunction with the accompanying drawings, wherein:

FIG. 1 is a side view of an rotorcraft, according to one example embodiment;

FIG. 2 is a side view of a panel, according to one example embodiment;

FIG. 3 is a cross-sectional view of the panel, taken from section lines 3-3 in FIG. 2, according to one example embodiment;

FIG. 4 is a perspective view of a composite core, according to one example embodiment;

FIG. 5 is a cross-sectional view of the composite core, taken from section lines 5-5 in FIG. 4, according to one example embodiment;

FIG. 6 is a schematic view of a method of manufacturing a composite core, according to one example embodiment;

FIG. 7 is a partially stylized view of a system for wrapping and assembling mandrels, according to example embodiment;

FIG. 8 is an exploded view of a mandrel winding jig, according to example embodiment;

FIG. 9A is a top view of a winding jig, according to example embodiment;

FIG. 9B is a top view of a winding jig, according to example embodiment;

FIG. 10 is a top view of a winding jig, according to example embodiment;

FIG. 11 is a top view of a winding jig, according to example embodiment;

FIG. 12 is a stylized, plan view of a mandrel being wrapped with uncured composite material, according to one particular embodiment;

FIG. 13 is a stylized, plan view of a mandrel being wrapped with uncured composite material, according to one particular embodiment;

FIG. 14 is a top view of a winding jig, according to example embodiment;

FIG. 15 is a detail view taken from FIG. 14, according to one example embodiment;

FIG. 16 is a detail view taken from FIG. 14, according to one example embodiment;

2

FIG. 17 is a perspective view of a cutting tool, according to one example embodiment;

FIG. 18 is a is an end view of a plurality of composite-wrapped mandrels stacked on a partial tool, according to one example embodiment;

FIG. 19 is an end view of a plurality of composite-wrapped mandrels assembled in a tool, according to one example embodiment;

FIG. 20 is a plan view of a plurality of composite-wrapped mandrels assembled in a tool, according to one example embodiment;

FIG. 21 is a cross-section view of a mandrel taken from FIG. 8, according to one example embodiment;

FIG. 22 is a perspective view of a bulk composite core, according to one example embodiment;

FIG. 23 is a detail view of the bulk composite core taken from FIG. 22, according to one example embodiment;

FIG. 24 is a perspective view of a wafer, according to one example embodiment;

FIG. 25 is a front view of a fixture for supporting a bulk composite core, according to one example embodiment;

FIG. 26 is a side view of a fixture for supporting a bulk composite core, according to one example embodiment;

FIG. 27 is a side view of a fixture for supporting a bulk composite core, according to one example embodiment;

FIG. 28 is a front view of a fixture for supporting a bulk composite core, according to one example embodiment;

FIG. 29 is a side view of a fixture for supporting a bulk composite core, according to one example embodiment;

FIG. 30 is a top view of a support system for supporting a bulk composite core, according to one example embodiment;

FIG. 31 is an end view of a support system for supporting a bulk composite core, according to one example embodiment;

FIG. 32 is a stylized exploded view of method for joining bulk composite cores, according to one example embodiment;

FIG. 33 is a side view of a bonded assembly of multiple bulk composite cores, according to one example embodiment;

FIG. 34 is a stylized exploded view of method for joining bulk composite cores, according to one example embodiment;

FIG. 35 is a stylized top view of a cutting path for cutting a wafer from a bulk composite core, according to one example embodiment; and

FIG. 36 is a side view of a cutting system for cutting a wafer from a bulk composite core, according to one example embodiment.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Illustrative embodiments of the system and method of the present disclosure are described below. In the interest of clarity, all features of an actual implementation may not be described in this specification. It will of course be appreciated that in the development of any such actual embodiment, numerous implementation-specific decisions must be made to achieve the developer's specific goals, such as compliance with system-related and business-related constraints, which will vary from one implementation to another. Moreover, it will be appreciated that such a development effort might be complex and time-consuming but would nevertheless be a routine undertaking for those of ordinary skill in the art having the benefit of this disclosure.

In the specification, reference may be made to the spatial relationships between various components and to the spatial orientation of various aspects of components as the devices are depicted in the attached drawings. However, as will be recognized by those skilled in the art after a complete reading of the present disclosure, the devices, members, apparatuses, etc. described herein may be positioned in any desired orientation. Thus, the use of terms such as "above," "below," "upper," "lower," or other like terms to describe a spatial relationship between various components or to describe the spatial orientation of aspects of such components should be understood to describe a relative relationship between the components or a spatial orientation of aspects of such components, respectively, as the device described herein may be oriented in any desired direction.

Referring now to FIG. 1 in the drawings, a rotorcraft 101 is illustrated. Rotorcraft 101 has a rotor system 103 with a plurality of rotor blades 105. The pitch of each rotor blade 105 can be managed in order to selectively control direction, thrust, and lift of rotorcraft 101. Rotorcraft 101 can further include a fuselage 107, anti-torque system 109, and an empennage 111.

Rotorcraft 101 is merely illustrative of the wide variety of aircraft, vehicles, and other objects that are particularly well suited to take advantage of the method and system of the present disclosure. It should be appreciated that other aircraft can also utilize the method and system of the present disclosure. Further, other vehicles and objects can utilize composite core manufactured by the system and method of the present disclosure. Illustrative embodiments can include wind turbine blades, sea based vehicles, radomes, enclosures, shelters, bridge decks, building facades, ground vehicles, rail vehicles, air vehicles, space vehicles, and manned or unmanned vehicles, to name a few.

Referring now also to FIGS. 2 and 3, a panel 113 on rotorcraft 101 is illustrative of a wide variety of structures that can include a core member configured as a lightweight means of generating strength and stiffness in the structure. Panel 113 is a composite assembly that can include an upper skin 301, a lower skin 303, and a composite core 305. Composite core 305 can be adhesively bonded to upper skin 301 and lower skin 303. It should be appreciated that panel 113 can take on a wide variety of contours and configurations.

Referring now also to FIGS. 4 and 5, composite core 401 is illustrated in a raw stock configuration. Composite core 305 (shown in FIG. 3), having implementation specific geometry, can be carved from composite core 401, for example. In another embodiment, composite core 401 is manufactured in a net shape such that a subsequent carving procedure is not required. Composite core 401 can be of a wide variety of materials and cell sizes. For example, in one embodiment composite core 401 is made from a carbon fiber and resin composite system. Composite core 401 includes a plurality of tubes 403 (only one tube labeled for clarity) arranged in a two-dimensional array. However, in one embodiment the tubes 403 can be selectively positioned such that the end portions are not in the same plane. Each tube 403 defines a passageway or "cell" 405 extending therethrough. Composite core 401 can comprise any suitable number, size, cross-sectional shape, and construction of tubes 403.

Each tube 403 of composite core 401 can include a plurality of reinforcement fibers disposed in a polymeric matrix. For example, tubes 403 may comprise fibers comprising one or more of carbon, graphite, glass, an aromatic polyamide (i.e., "aramid") material, a variant of an aromatic polyamide material (e.g., a polyparaphenylene terephthalamide material, such as Kevlar® by E. I. du Pont de Nemours and Com-

pany of Richmond, Va.), or the like. The scope of the present disclosure, however, encompasses fibers comprising any suitable material or combination of materials. The polymeric matrix may comprise any suitable resin system, such as a thermoplastic or thermosetting resin for example. Exemplary resins include epoxy, polyimide, polyamide, bismaleimide, polyester, vinyl ester, phenolic, polyetheretherketone (PEEK), polyetherketone (PEK), polyphenylene sulfide (PPS), and the like.

The fibers of tubes 403 may be oriented in one or more directions and may be woven or unwoven. It should be appreciated that tube 307 may alternatively only include fibers arranged in a single direction, such as a uniaxial or helical fiber configurations. In yet another embodiment, a first ply comprises fibers and a second ply comprises fibers, such that the second ply is laid-up over the first ply.

Referring now also to FIG. 6, a method 601 of manufacturing a composite core, such as composite core 401, is schematically illustrated. Method 601 can include a step 603 of configuring a plurality of mandrels. A step 605 can include wrapping a composite material around each mandrel. A step 607 can include assembling the wrapped mandrels. A step 609 can include curing the composite material to form a cured core member. A step 611 can include cooling the mandrels and removing the mandrels from the cured core member. Each step of method 601 is described in further detail herein.

Referring to FIG. 21, a cross-sectional view through a mandrel 701 is illustrated. Step 603 includes configuring a plurality of mandrels. In the illustrated embodiment, mandrel 701 is a metallic mandrel, such an aluminum material. Mandrel 701 is configured having a material with a relatively low coefficient of thermal expansion (CTE). In the illustrated embodiment, mandrel 701 is preferably cured in a tool that utilizes a bladder or other device to apply pressure from the exterior. However, it should be appreciated that method 701 can also be configured with a material having a desired amount of CTE so that curing pressure is derived from a thermal expansion of the mandrels within a confining tool.

Mandrel 701 may be configured with a hollow portion 703 extending through the centerline length of mandrel 701, forming a body portion 705 between hollow portion 701 and outer surface 707. Mandrel 701 is configured so that during the curing process of the composite core 401, the temperature of each mandrel 701 is increased such that body portion 705 volumetrically expands uniformly both in an inward direction and an outward direction, until outer surface 707 is bounded by its nearest neighbor mandrel, at which point the pressure exerted by mandrel 701 on its nearest neighbor mandrel remains relatively constant, and the thermal expansion of body portion 705 continues primarily in inward direction. The degree of thermal expansion each mandrel 701 is dependent upon the CTE of the material of each mandrel 701. The geometry of mandrel 701 can be selected to tailor the physical properties of mandrel 701 and the resultant composite core 401. Further, the geometry of mandrel 701 can be selected to tailor the strength/stiffness of the mandrel 701. Further, the wall thickness of body portion 705, as well as the geometry of hollow portion 703, can be selectively controlled to produce a desired thermal expansion profile. For example, a mandrel having a smaller hollow portion 703 would provide a higher external pressure than mandrel 701. In the illustrated embodiment, hollow portion 703 is of a cylindrical shape; however, it should be appreciated that other embodiments may have non-cylindrical shapes.

Each mandrel 701 is configured with a hollow portion 703 which allows hot air to be ducted therethrough during the cure cycle, as discussed further herein. However, it should be

5

appreciated that an alternative embodiment of mandrel **701** does not include a hollow portion **703**. It should be appreciated that mandrel **701** is merely illustrative of a wide variety of mandrel configurations contemplated. Even though the exterior shape of the mandrels are illustrated as hexagonal, the present disclosure includes mandrels having other exterior shapes, such as square, rectangular, triangular, to name a few examples. Further, it should be appreciated that the hollow portion within the mandrels can be any variety of shape, or shapes. The exact shape of the hollow portion is implementation specific.

In one example embodiment, a Teflon® material, or other bond resistant material or coating, can be used to prevent the composite material from bonding to the exterior surface of mandrel **701** during the cure cycle. As such, each mandrel **701** can include a layer **709** of the bond resistant material adjacent to the outer surface **707** of each mandrel **701**.

Referring again to FIG. 6, step **605** includes wrapping composite material around each mandrel, such as mandrel **701**. The exact method of wrapping or otherwise depositing the uncured composite material on the exterior surface of each mandrel is implementation specific. In the preferred embodiment, one or more steps of method **601** are performed by an automated system; however, it should be appreciated that any of the steps can be performed manually.

Referring also to FIG. 7, a system **801** for at least partially performing one or more steps of method **601** is illustrated. Further, system **801** is particularly well suited for performed steps **605** and **607**. Step **605** includes wrapping composite material around each mandrel. Step **607** includes assembling the wrapped mandrels. Each of steps **605** and **607**, as well as system **801**, are further described herein.

System **801** can include a hopper **803** configured to house a plurality of mandrels **701**. Each mandrel **701** can be selectively deployed and captured by a winding jig **805**. For example, each mandrel **701** can be released onto a conveyor **807** and picked up by the arms of winding jig **805**.

Referring also to FIG. 8, an embodiment of winding jig **805** is illustrated. Winding jig **805** is configured to position and retain mandrel **701** for the depositing of composite material thereon. It should be appreciated that winding jig **805** can take on a variety of implementation specific configurations. In one embodiment, winding jig **805** can include a driver **809** and a support member **811**. Adapters **813a** and **813b** are operably associated with driver **809** and support member **811**, respectively. A coupling **815a** is positioned between driver **809** and a first end portion of mandrel **701**. Similarly, a coupling **815b** is positioned between support member **811** and a second end portion of mandrel **701**.

Winding jig **805** is configured to operably secure mandrel **701** between couplings **815a** and **815b**. Couplings **815a** and **815b** have similar geometry to that of mandrel **701**. Further, winding jig **805** is configured such that the geometry of couplings **815a** and **815b** are aligned with mandrel **701** during the composite material winding process. In the illustrated embodiment, driver **809** is configured to drive the rotation of adapters **813a** and **813b**, couplings **815a** and **815b**, and mandrel, while support member **811** is configured to provide freewheeling support. In an alternative embodiment, mandrel **701** and couplings **815a** and **815b** are held stationary while a device operates to place the composite material about the mandrel and couplings **815a** and **815b**, as discussed further herein. It should be appreciated that winding jig **805** is merely illustrative of a fixture that can be used to facilitate the depositing of composite material onto mandrel **701** in step **605** of method **601**.

6

Referring also to FIG. 9A, one non-limiting example embodiment of winding jig **805** for performing at least step **605** of method **601** is illustrated. Winding jig **805** is mounted to a platform **817** that can be translated along a prescribed path. A first end portion of slit **819** can be secured to a mount **821** that is secured to platform **817**. Slit **819** is positioned through an opening **823** in coupling **815b**. A second end portion of slit **819** can remain part of a roll **827** of composite material. In one embodiment, a plurality of cutting members cut roll **827** of composite material into a plurality of slits **819** at prescribed widths, each slit **819** being fed to different winding jigs **805**. Platform **817** is biased in direction **825** by a constant tension member such that slit **819** is held in tension. Mount **821** and roll **817** are positioned so that slit **819** is oriented at a desired angle relative to mandrel **701**. In the illustrated embodiment, the desired angle of slit **819** is 45 degrees; however, slit **819** can be oriented at any desired angle.

Referring also to FIG. 9B, the operation of winding jig **805** is illustrated. Driver **809** is operated so as to cause mandrel **701** to rotate, which causes slit **819** to wrap around mandrel **701**. As slit **819** wraps around mandrel **701**, platform **817** is pulled toward roll **817** in direction **829** while the wrap angle is maintained.

Referring also to FIG. 10, another example embodiment of a winding jig **1005** for wrapping composite material on each mandrel **701** in step **605** is illustrated. Winding jig **1005** is substantially similar to winding jig **805**; however, winding jig **1005** is configured so that mandrel **701** is held stationary while a material placement head **1001** moves around mandrel **701**, as well as translates along an axis of mandrel **701**, such as in directions **1007** and **1009**, respectively. Material placement head **1001** is configured to feed composite material while moving in a prescribed path. In such an embodiment, slit **819** can be secured at a stationary mount **1003** so that slit **819** can be placed in tension by material placement head **1001** as slit **819** is wrapped around mandrel **701**.

Referring also to FIG. 11, another example embodiment of a winding jig **1105** for wrapping composite material on each mandrel **701** in step **605** is illustrated. Winding jig **1105** is substantially similar to winding jig **1005**; however, winding jig **1105** is configured so that mandrel **701** is rotated in a direction **1107** while material placement head **1001** translates along an axis of mandrel **701** corresponding with direction **1009**. In such an embodiment, slit **819** can be secured to coupling **815a**, for example, so that tension can be formed in slit **819** as material placement head **1001** translates and mandrel **701** rotates.

In another example embodiment, the winding jig is configured to translate along a direction corresponding with the axis of mandrel **701** while material placement head **1001** rotates but does not translate.

It should be appreciated that the winding jig can be configured in any combination of the configurations described herein. For example, mandrel **701** can rotate in a first rotational direction while material placement head **1001** rotates around mandrel **701** in an opposite direction to that of the first rotational direction. Further, either mandrel **701** can translate along its axis or the material placement head can translate in a direction corresponding to the mandrel axis, or any combination thereof.

It should be appreciated that the exact system and method for depositing raw composite material on mandrel **701** can be dependent at least upon the material form of the raw composite material.

Referring also to FIG. 12, one technique of wrapping uncured composite material around mandrel **701** utilizes a

filament winding process. A continuous, resin-impregnated fiber **1401**, extending from a filament winding machine **1403**, is wound about mandrel **701**. The resin can be either a thermosetting or thermoplastic resin and becomes the polymeric matrix of tube **403** upon curing. The material placement process may be conducted in a variety of processes; for example, mandrel **701** can move axially while a spool of fiber **1401** rotates around the mandrel **701**, as indicated by an arrow **1407**. Alternatively, a spool or a plurality of spools of material could rotate around mandrel **701**. Relative motion of the material dispensing mechanism to mandrel **701** is inferred. As fiber **1401** is wound onto mandrel **701** by filament winding machine **1403**, a helical shaped pattern is formed. One or more plies **1409** of fiber **1401**, in desired orientations with respect to mandrel **701**, are wound onto mandrel **701** to form the basic geometry of tube **403**. The angle of which fiber **1401** is wound about mandrel **701** may vary along the length of the mandrel **701** in order to customize the strength of core **401**. For example, the angle of the fiber **1401** may be dynamically changed during the material placement process in order to customize a compressive strength of the core. Note that, in the illustrated embodiment, mandrel **701** exhibits a size and shape corresponding to cell **405** (see FIG. 4 or 5). It should be further noted; however, that the present disclosure is not limited to the particular illustrated configurations of filament winding machine **1403** or mandrel **701**. Mandrel **701** and the one or more plies **1409** that have been filament wound onto mandrel **701** are subsequently assembled with other mandrels and plies, as will be discussed in greater detail herein, to form core **401** (shown in FIG. 4). It should further be appreciated that upon cutting of plies **1409** and the mandrel **701**, the material may have a tendency to un-wind. A band of material, potentially adhesive or fibrous, may be used to keep fiber **1401** from unraveling upon cutting of the plies **1409** and the mandrel **701**. An adhesive material with unidirectional fibers could be used to band the fiber **1401** on mandrel **701**. Further, the band can be selectively located and used to provide extra support for a subsequent post processing procedure of the core, such as a machining process.

In yet another example technique of performing step **605** of method **601**, shown in FIG. 13, wrapping uncured composite material around mandrel **701** is performed using a fiber placement process. A continuous, resin-impregnated tow **1301** (only one labeled for clarity) of approximately, but not limited to, 1000 fibers is applied to a mandrel **701** by a fiber placement machine **1305**. It should be appreciated that tow **1301** may also be portions of a full tow; for example, tow **1301** may be a half tow of 500 fibers. In lieu of a tow **1301**, a tape of fibers, cut to a prescribed width, may be used. A pre-cut tape of fibers may be referred to as a "slit-tape." A slit-tape allows the user to more closely control the width dimension, as compared to a tow of fibers. Exemplary prescribed widths of slit-tape include $\frac{1}{8}$ " and $\frac{1}{4}$ ", to name a few. The resin can be a thermosetting or thermoplastic resin, to name two examples, and becomes the polymeric matrix of tube **403** upon curing. During the fiber placement process, mandrel **701** can move axially while tow **1301** rotates around the mandrel **701**, as indicated by an arrow **1307**. As tow **1301** is applied to mandrel **701** by fiber placement machine **1305**, a helical shaped pattern is formed. One or more plies **1309** of tow **1301**, in desired orientations with respect to mandrel **701**, are wound onto mandrel **701**. In one embodiment, one or more non-helical plies layers may be assembled on mandrel **701** to customize mechanical properties in certain directions. It should be appreciated that more than one tow **1301** or slit-tape of different materials may be used. Note that, in the illustrated embodiment, mandrel **1303** exhibits a size and

shape corresponding to cell **405** (see FIG. 4 or 5). It should be further noted, however, that the present disclosure is not limited to the particular illustrated configurations of fiber placement machine **1305** or mandrel **701**. Mandrel **701** and the one or more plies **1309** that have been fiber placed onto mandrel **701** are subsequently assembled with other mandrels and plies, as will be discussed in greater detail below, to form core **401** (shown in FIG. 4).

Referring now also to FIGS. 14-16, one example embodiment of step **605** includes wrapping mandrel **701** with a broadgood form of slit **819** in such a procedure that results in solid passageway or "closed cell" geometry. Namely, the broadgood form of slit **819** has a width **W1** that is selected to prevent a gap or space in the slit **819** after slit **819** is wrapped around mandrel **701**. Further, as slit **819** is wrapped around mandrel **701**, a continuous seam **831** is formed; however, seam **831** is not a gap or space in the material, rather seam **831** represents an abutment of helically wrapped material, such as slit **819**, which is an example of a customized width broadgood composite material. In contrast, the wrapping of a mandrel with composite material that produces a gap or space in the material, or an "open cell" geometry, as described with regard to FIGS. 12 and 13, can have undesirable attributes in certain implementations. For example, the "open cell" embodiment may be limited by the widths of the tows or slits having to be consistent, resulting in having only a fixed whole number of tows for a given spacing and angle, and the gaps having to be a uniform width. The result is only having a fixed whole number of materials for a given spacing and angle. The angle with which the tow or slit is wrapped cannot be varied infinitely and still retain a specific tow or slit width and spacing. Furthermore, an "open cell" geometry core can be undesirable in some panel implementations because of insufficient bond surface at the core/skin interface. Further, for a given mandrel geometry there are a limited number of tow or slit width and gap combinations that will satisfy construction of the core tube for a given wrap angle.

Referring in particular to FIGS. 15 and 16, the orientation fibers **1501** of slit **819** is implementation specific. In the embodiment illustrated in FIG. 15, fibers **1501** are unidirectional such that all the fibers extend in a direction corresponding with the length of the slit **819**. In the embodiment illustrated in FIG. 16, fibers **1501** are multidirectional so as to form a fabric configuration.

Still referring to FIGS. 14-16, a nominal width **W1** of slit **819** can be calculated by multiplying the circumference of the exterior surface of mandrel **701** by the cosine of the wrap angle **A1**. One major advantage of using slit **819** to wrap mandrel **701** without material gaps is that the angle **A1** can be customized for the core implementation while simply adjusting for the width **W1** of slit **819**. Furthermore, the slit **819** can be cut off from a much wider roll of bulk raw material, such that the customization of width **W1** can be simply a matter of adjusting the cutting tool to provide the implementation specific width. Customizing the angle **A1** allows a user to tailor the physical properties of the core by orienting the fibers **1501** in a direction to produce said physical properties. Referring briefly to FIG. 17, an example cutting tool **1701** is illustrated. Cutting tool **1701** can have a plurality of cutting members **1703**, such as blades, that can be oriented to cut slits **819** at prescribed widths from a raw material roll **1705**. Each slit **819** can be communicated to a winding jig **805**, as discussed further herein. Cutting tool **1701** is especially well suited for cutting slits **819** having unidirectional fibers such that cutting members **1703** cut the raw material along between adjacent fibers. In contrast, a cutting tool having a male/female press

cutting members may be better suited for cutting slits **819** having multidirectional fibers.

Still referring to FIGS. **14-16**, the “closed cell” geometry core produced by wrapping broadgood composite material in step **605** of method **601** enables the use of much thinner and lighter composite material, thereby producing a core with very low density. Further, the “closed cell” geometry core can have significantly higher stiffness and strength than is achievable with “open cell” geometry core. Furthermore, “closed cell” geometry core is fully tailorable.

In another embodiment of step **605** of method **601**, mandrel **701** is wrapped multiple times to produce multiple layers of composite material layers. In such an embodiment, the fiber orientation, wrap angle, and/or wrapping direction can be varied to produce tailored mechanical and physical properties.

In some situations it may be desirable to provide ventilation and/or drainage in the composite core, such as in a wing member of an aircraft that also functions as a fuel tank. In such an embodiment, step **605** of method **601** can also include creating perforations in the raw material or slit **819**. The perforations can be created by any variety of methods; one method can be running the raw material or slit **819** over a spiked wheel or spiked roller support, for example.

Referring again to FIGS. **6** and **7**, step **607** of method **601** includes assembling the wrapped mandrels. Step **607** can further include assembling and inserting the wrapped mandrels in a tool or other fixture. The exact configuration of the tool is implementation specific. Referring now also to FIGS. **18-20**, an example of a tool **1201** is illustrated. Tool **1201** is configured to produce a hexagonal shaped core member; however, tool **1201** can be configured to provide any desirable shape. For example, alternative shapes of tool **1201** can be configured to produce circular, square, rectangular, or even part customized core shapes. In the illustrated embodiment, the plurality of mandrels **701** having wrapped composite material are assembled onto partial tool members **1203a-1203f** in a pyramid shape. In one embodiment, system **801** is configured to automate the assembly and stacking of wrapped mandrels, as shown in FIG. **7**. In another embodiment, the assembly and stacking of wrapped mandrels can be performed manually. Each partial tool member **1203a-1203f** can include apertures **1205** to control and tailor any thermal expansion of the partial tool member **1203a-1203f** during the cure process. In one embodiment, each partial tool member **1203a-1203f** is stacked with seven levels of wrapped mandrels. Upon assembling each partial tool member **1203a-1203f** and their wrapped mandrels, one additional wrapped mandrel **1205** is located in the center. However, it should be appreciated that each partial tool member **1203a-1203f** may be stacked with wrapped mandrels and assembled in a variety of ways.

In one example embodiment, tool **1201** includes a bladder **1207** that is configured to inflate to provide a prescribed inward pressure upon the assembly of wrapped mandrels **701**. However, it should be appreciated that the present disclosure contemplates other methods of providing pressure to the composite material wrapped around each mandrel **701** during the curing process, such as mechanical pressure generating devices.

In another embodiment, curing pressure can be generated by the thermal expansion of the mandrels **701**. In such an embodiment, tool **1201** can include a rigid constraining structure in lieu of bladder **1207**. The heating of the mandrels **701** causes thermal expansion, which generates pressure at the composite material between mandrels **701**.

Tool **1201** can include a blower **1209** for generating an airflow **1211** and evenly distributing the airflow through the interiors of the plurality of mandrels **701**. In an alternative embodiment, a fluid, such as an oil, is circulated through the interiors of the plurality of mandrels **701**. Step **609** can include heating the wrapped mandrels within tool **1201** for a prescribed duration in accordance with the cure requirement of the composite system. An oven can be used to generate that requisite heat, for example. Airflow **1211** can improve the heating rate and heat distribution to the composite material wrapped around each mandrel **701**, as such; it is particularly desirable to have an interior opening through each mandrel **701** that is sized to accommodate a prescribed amount of airflow. Bladder **1207** can be controlled by a controller **1213** so as to tailor the amount and timing of pressure exerted at the cell walls of composite material between mandrels **701** within tool **1201**.

Referring again to FIG. **6**, step **609** of method **601** includes curing the composite material wrapped around the mandrels **701** to form the cured composite core **401**. As discussed further above, the uncured composite material around each mandrel **701** is cured by subjecting the assembly to the requisite temperature and pressure. As discussed above, the temperature and rate of temperature change of the composite material can be controlled in part by blowing hot air through the interior of mandrels **701**. During the curing process of step **609**, the temperature and pressure exerted upon the composite material is implementation specific. Bladder **1207** can be controlled by controller **1213** so as to tailor the amount and timing of pressure exerted at the cell walls of composite material between mandrels **701** within tool **1201**. For example, bladder **1207** can be controlled by controller **1213** to change the amount of pressure during a viscosity change of the resin in the composite material.

After the cure cycle is complete, a composite core **401** is achieved as the uncured composite material around each mandrel **701** becomes rigidly bonded to each adjacent tube **403**. It should be noted that composite core **401** that is formed by wrapping mandrels **701** with unidirectional fiber slits **819** at a prescribed angle produces composite core **401** that has cross-linked fibers at the cell walls. For example, multiple mandrels **701** wrapped at a wrap angle of +45 degrees with slits **819** having unidirectional fibers will produce cured composite core **401** with cell walls having two plies of fibers at 90 degrees to each other. This unique result of the method and system of the present disclosure produces a very lightweight and strong composite core **401**.

Still referring to FIG. **6**, step **611** of method **601** includes cooling mandrels **701** and removing mandrels **701** from the composite core **401**.

It should be appreciated that method **601**, and the process related systems disclosed above are merely illustrative of one exemplary method for manufacturing composite core **401**. Furthermore, the post-cure processing methods and systems disclosed herein can be utilized for post-cure processing of composite core **401** made from any suitable manufacturing process.

Referring to FIGS. **22** and **23**, a bulk composite core **2201** has an outer hexagonal shape corresponding with a tool having an inner hexagonal shape, such as tool **1201** illustrated in FIG. **19**. Further, bulk composite core **2201** is substantially similar to composite core **401**, discussed further herein. For example, bulk composite core **2201** has a plurality of tubes **2203** forming a plurality of cells. The post-cure processing methods and systems of the present disclosure are discussed herein with regard to bulk composite core **2201**; however, it should be appreciated that the post-cure processing methods

11

and systems disclosed herein are applicable to other bulk composite core shapes, as well composite core having other cell member shapes.

The present disclosure includes methods and systems for efficiently and effectively cutting wafers from the bulk composite core **2201**. Bulk composite core **2201** is typically produced with an overall size that is larger than required for an implementation; for example, bulk composite core **2201** can have a width **W1** of approximate 18 inches and tube lengths **L1** of 30 inches. However, it should be appreciated that composite core **2201** can be of any practical size.

Referring now also to FIG. 24, one embodiment of a wafer **2401** is illustrated. Wafer **2401** is a product cut from bulk composite core **2201**. In the illustrated embodiment, the tube lengths **L2** are approximately $\frac{1}{2}$ inch. However, it should be appreciated that tube lengths **L2** can be of any implementation specific size. For example, a wafer **2401** for use in a wing structure may have tube lengths **L2** of 8 inches. One object of the present disclosure is to efficiently achieve a high yield of quality wafers **2401** from a bulk composite core **2201**.

It should be appreciated that wafers **2401** may be cut from bulk composite core **2201** using any suitable cutting device. For example, exemplary cutting devices may include a band saw, a circular cutting blade, a circular grinding blade, a rope saw, to name a few examples.

Referring again to FIGS. 22 and 23, bulk composite core **2201** has an outer shape of a hexagon that can particularly benefit from the methods and systems disclosed herein. Since the hexagonal bulk composite core **2201** has a non-uniform cross-section, cutting induced forces (such as compression along **W1**) can cause distortion that may adversely affect the quality of a wafer **2401** cut therefrom. Not only may bulk composite core **2201** have a tendency to compress during the cutting operation, but bulk composite core **2201** may also have a tendency to torsionally twist when subjected to cutting forces.

Referring now also to FIGS. 25 and 26, a fixture **2501** configured for supporting a bulk composite core **2201** during a cutting operation, is illustrated. Fixture **2501** includes partial sections **2503a-2503f** that collectively form an outer support for bulk composite core **2201**. Each partial section **2503a-2503f** is a rigid member that can be coupled together to form interior surfaces that are adjacent to the exterior surfaces of bulk composite core **2201**. In the illustrated embodiment, the exterior surfaces of bulk composite core **2201** are outer flat surfaces of the outer hexagonal shaped tube members **2203**. Thus, the interior surfaces of partial sections **2503a-2503f** mirror the outer flat surfaces of the outer hexagonal shaped tube members **2203**. Fixture **2501** can be mounted to a support **2505** for stabilization.

During operation, bulk composite core **2201** can be positioned within fixture **2501** so as to partially expose a desired amount so that a cutter **2601** can cut a wafer **2401** to a desired length **L2**. In the illustrated embodiment, cutter **2601** is a band saw blade; however, cutter can be any device capable of cutting bulk composite core **2201**. As cutter applies cutting relates forces upon bulk composite core **2201** adjacent to an exposed portion of fixture **2501**, fixture **2501** keeps composite core **2201** from compressing as well as torsional twisting.

Referring now also to FIG. 27, an alternative embodiment of fixture **2501** is illustrated as a fixture **2701**. Fixture **2701** is substantially similar to fixture **2501**, except for having a multiple fixture segments, such as fixture segments **2703** and **2705**. During operation, cutter **2601** can cut the bulk composite core **2201** between the fixture segments **2703** and **2705**. Fixture **2701** may be particularly well suited for support of bulk composite core **2201** for the cutting of relatively large

12

wafers **2401**. Further, fixture **2701** can have any number of fixture segments that have any number of sizes. For example, it may be desirable to cut multiple wafers **2401** from one or more bulk composite cores **2201** at the same time, in which fixture **2701** can be adapted accordingly.

Referring now also to FIGS. 28 and 29, a fixture **2801** for supporting a bulk composite core **2201** for the cutting of wafers **2401** therefrom is illustrated. In the illustrated embodiment, fixture **2801** includes a plurality of mandrels **2803** that can be affixed to a support **2805**. Mandrels **2803** are arranged in a geometry pattern so as to align with the center of tubes **2203**. Further, each mandrel **2803** has a geometry that corresponds with the geometry of each tube **2203** in the bulk composite core **2201**. The mandrels **2803** are spaced to allow for the bulk composite core **2201** to slide onto the mandrels **2803**, which provide support during a cutting operation, as depicted in FIG. 29.

In one embodiment, mandrels **2803** are solid rigid mandrels that are configured to support a main body portion of bulk composite core **2201** while a wafer **2401** is cut near an end portion of bulk composite core **2201** that does not have mandrels **2803** extending therethrough. In another embodiment, mandrels **2803** are sacrificial such that the mandrel material is a material that can be easily cut through, such as a foam, so that the cutter cuts not only through the bulk composite core **2201** but also the mandrels **2803**. Such a configuration not only prevents the bulk composite core **2201** from distorting during the cutting process, but also can reduce localized vibration due to cutting. Furthermore, the sacrificial mandrel embodiment of fixture **2801** may not include support **2805**.

Referring now also to FIG. 30, another embodiment of a system configured to support a bulk composite core **2201** while a wafer **2401** is cut therefrom is illustrated. In the illustrated embodiment, bulk composite core **2201** is placed in a container **3001** and then surrounded by a compound **3003** that can bond to the outer surface of bulk composite core **2201** and solidify, such as a potting compound or expanding foam, to name a few examples. Bulk composite core **2201** with compound **3003** bonded thereto can be removed from container **3001** so that one or more wafers **2401** can be cut therefrom, as further described herein. Compound **3003**, in a cured state, provides rigid support to bulk composite core **2201** during a wafer cutting process. In one embodiment, the compound **3003** can be removed from the exterior surfaces of the wafer **2401** during a cleaning operation. In another embodiment, the outer cells are machined away from the internal portion of wafer **2401** such that any composite core material contaminated with compound **3003** is removed.

Referring now also to FIG. 31, another embodiment of a system configured to support a bulk composite core **2201** while a wafer **2401** is cut therefrom is illustrated. In the illustrated embodiment, a composite wrap **3101** can include one or more plies of composite material wrapped around a cured bulk composite core **2201**. The composite wrap **3101** is cured in accordance with the implementation specific composite system. For example, the composite wrap **3101** can be cured in a room temperature environment or an oven. In an alternative embodiment, composite wrap **3101** is laid up when bulk composite core **2201** is uncured. For example, an uncured composite wrap **3101** can be laid up around an assembly of uncured composite wrapped mandrels, and then co-cured in a tool, such as tool **1201** illustrated in FIG. 19.

Composite wrap **3101** is configured to provides strength and stiffness to bulk composite core **2201** while wafer **2401** is cut therefrom. Further, since deformation due to cutting induced torque occurs from the outside, composite core **2201**

13

is particularly useful for resisting torque deformation. After the wafer **2401** is cut from the bulk composite core **2201**, the composite wrap **3101** can be machined away. For example, the outer cells can be machined away from the internal portion of wafer **2401** such that composite wrap **3101** is removed.

Referring again briefly to FIG. 26, the method of cutting wafers **2401** from bulk composite core **2201** can include cutting off a wafer **2401**, then repeatedly repositioning the remaining bulk composite core **2201** and cutting additional wafers **2401**. However, as the remaining portion of the bulk composite core **2201** becomes shorter, the effectiveness of fixture **2501** can be compromised. For example, fixture **2501** can lose effectiveness when the length L1 of the bulk composite core **2201** is less than 50% of the width W1. By way of example, if the width W1 is 18 inches, then a length L1 of less than 9 inches may be undesirable. Hence, there is a need for a method and system for utilizing and cutting one or more wafers **2401** from relatively short sections of bulk composite core **2201**.

Therefore, the present disclosure also includes a system and method for joining a plurality of bulk composite cores **2201** end to end. The joining of multiple bulk composite cores **2201** prevents the waste of material that couldn't otherwise be accurately supported by a support tool, such as fixture **2501** for example. Further, joining multiple bulk composite cores **2201** can result in a more efficient wafer cutting operation. For example, a long assembly of bulk composite cores **2201** can be fed through fixture **2501** as cutter **2601** can continuously operate. After a wafer **2401** is cut, cutter **2601** can reposition while the remaining bulk composite core **2201** translates relative to fixture **2501** to expose a desired portion of bulk composite core **2201** for wafer cutting. The cutter **2601** can then make another cut to produce another wafer **2401** at a desired length L2. In one embodiment, once a bulk composite core **2201** is cut down such that the remaining uncut portion is too short to be properly supported by the fixture, the remaining uncut portion can be removed and joined with another bulk composite core **2201**.

Referring now also to FIG. 32, the joining of multiple bulk composite cores is schematically illustrated. A first bulk composite core **2201a** has a first bonding surface **3201a** and a second bulk composite core **2201b** has a second bonding surface **3201b**. An adhesive can be applied to the first bonding surface **3201a** and/or the second bonding surface **3201b** in any appropriate process. For example, if the bond qualities of a film adhesive are desired, then the film adhesive can be reticulated on the surface network of at least one of the first bonding surface **3201a** or the second bonding surface **3201b**. In another embodiment, a paste adhesive can be applied on the surface network of at least one of the first bonding surface **3201a** or the second bonding surface **3201b**. A plurality of mandrels **2803** that each have a geometry similar to the interior of each cell can be used to assure that the cells of first bulk composite core **2201a** align with the cells of second bulk composite core **2201b**. The mandrels **2803** extend into corresponding cells of the first bulk composite core **2201a** and of second bulk composite core **2201b** for alignment thereof. A release agent can be used to prevent the adhesive from bonding to the mandrels **2803**. The first bonding surface **3201a** of the first bulk composite core **2201a** is butted up against the second bonding surface **3201b** of the second bulk composite core **2201b** and bonded together with the adhesive. During the adhesive curing process, heat may be applied, depending upon the cure requirements of the particular adhesive being used. Further, pressure can be generated at the bondline by pressing first bulk composite core **2201a** and second bulk composite core **2201b** together. After the adhesive is cured,

14

the mandrels **2803** may be removed. In another embodiment, the mandrels **2803** are moved to toward an exposed end of the core to be used in another joining process.

Referring now also to FIG. 33, a bulk composite core assembly **2201c** is illustrated. Bulk composite core assembly **2201c** is the result of first bulk composite core **2201a** adhesively joined with second bulk composite core **2201b**.

Referring now also to FIG. 34, another embodiment of joining multiple bulk composite cores is schematically illustrated. In the illustrated embodiment, an adhesive is applied around the circumference of each mandrel **2803** at a midsection portion **3403**. In one embodiment, an adhesive film is wrapped around the midsection portion **3403** of each mandrel **2803**. The first bulk composite core **2201a** and the second bulk composite core **2201b** are assembled with the mandrels **2803** such that that first surface **3401a** of the first bulk composite core **2201a** is butted up against the second surface **3401b** of the second bulk composite core **2201b**, thereby causing a portion of first bulk composite core **2201a** and second bulk composite core **2201b** to overlap a portion of the adhesive around each mandrel **2803**. During an adhesive curing process, heat may be applied, depending upon the cure requirements of the particular adhesive being used. The mandrels can thermal expand during the curing process, thereby forcing the adhesive to the cell walls of the first bulk composite core **2201a** and second bulk composite core **2201b**. Each mandrel **2803** can have an exterior surface that resists bonding from the adhesive, so that the mandrels **2803** can be removed after the adhesive is cured. For example, a release agent can be applied to the mandrels **2803**. In another embodiment, the mandrels **2803** remain with the bulk composite core assembly **2201c**. In such an embodiment, mandrels **2803** can be bonded together with the first bulk composite core **2201a** and second bulk composite core **2201b**. Furthermore, the mandrels **2803** may have a length similar to the adhesive width.

Referring now to FIGS. 35 and 36, another embodiment of a method and system for cutting a wafer **2401** from bulk composite core **2201** is schematically illustrated. In the illustrated embodiment, a circular cutting saw **3601** having a diameter smaller than the width of the cell wall width (from flat to flat) is utilized to progressively cut certain cells from the inside out to produce a wafer **2401**. For example, a computer numerical control (CNC) machine **3603**, or the like, can be programmed with a cutting path **3501**. In the illustrated embodiment, cutting path **3501** has a first point **3503** at the center of the bulk composite core **2201**. The circular cutter moves to the center of starting point **3503**, then moves into the bulk composite core **2201** to a depth D1 which corresponds with the desired length L1 of wafer **2401**. The circular cutter then moves toward a cell wall, thereby cutting into the cell wall, then moves around until all of the cell walls of the cell at starting point **3503** have been cut. Next, the circular cutter lifts out of the cell, and then proceeds to the next cell along the cutting path **3501** until the wafer **2401** is completely cut with the cutting of the last cell at last point **3505**. In the illustrated embodiment, the cells marked with "N" **3507** are not cut by the circular cutter, rather cells marked with "N" **3507** do not require cutting because the cell walls of surrounding cells are cut therethrough. As such, the cutting path **3501** is an efficient path for cutting a wafer **2401** out of bulk composite core **2201**. Further, by cutting the cells walls individually from the inside, distortion from cutting loads are minimized, thus reducing or eliminating the need for a fixture. Bulk composite core **2201** can be temporarily fixed, by taping or the like, to a tool **3605** for support thereof.

15

In one embodiment, the wafer **2401** is cut from bulk composite core **2201** at a constant depth D1; however, in another embodiment, the CNC machine can be programmed such that the circular cutter creates a wafer **2401** at a profiled depth D1 having any variety of implementation specific contours.

The particular embodiments disclosed herein are illustrative only, as the system and method may be modified and practiced in different but equivalent manners apparent to those skilled in the art having the benefit of the teachings herein. Modifications, additions, or omissions may be made to the system described herein without departing from the scope of the invention. The components of the system may be integrated or separated. Moreover, the operations of the system may be performed by more, fewer, or other components.

Furthermore, no limitations are intended to the details of construction or design herein shown, other than as described in the claims below. It is therefore evident that the particular embodiments disclosed above may be altered or modified and all such variations are considered within the scope and spirit of the disclosure. Accordingly, the protection sought herein is as set forth in the claims below.

To aid the Patent Office, and any readers of any patent issued on this application in interpreting the claims appended hereto, applicants wish to note that they do not intend any of the appended claims to invoke paragraph 6 of 35 U.S.C. § 112 as it exists on the date of filing hereof unless the words “means for” or “step for” are explicitly used in the particular claim.

The invention claimed is:

1. A method of joining a first bulk composite core and a second bulk composite core, the method comprising the steps of:

applying an adhesive to a first surface network of the first bulk composite core, the first surface network being an exposed surface at a first termination end of a plurality of cell members of the first bulk composite core;

inserting a plurality of mandrels into the plurality of cell members of the first bulk composite core and a plurality of cell members of the second composite core, thereby aligning the cell members of the first bulk composite core to the cell members of the second bulk composite core, the second bulk composite core having a second surface network that is an exposed surface at a first termination end of a plurality of cell members of the second bulk composite core;

pressing together the first surface network of the first bulk composite core and the second surface network of the second bulk composite core with the adhesive located therebetween; and

curing the adhesive.

2. The method according to claim **1**, the step of applying the adhesive to the first surface network of the first bulk composite core comprising reticulating a film adhesive onto the first surface network of the first bulk composite core.

3. The method according to claim **1**, the step of applying the adhesive to the first surface network of the first bulk composite core comprising pasting a paste adhesive onto the first surface network of the first bulk composite core.

4. The method according to claim **1**, wherein the first bulk composite member and second bulk composite member each have a substantially hexagonal outer geometry.

5. The method according to claim **1**, wherein each cell member has a hexagonal shaped geometry.

6. The method according to claim **1**, wherein each mandrel has a hexagonal shaped geometry.

7. The method according to claim **1**, further comprising the step of:

removing the plurality of mandrels.

16

8. A method of joining a first bulk composite core and a second bulk composite core, the method comprising the steps of:

applying an adhesive at a midportion of each of a plurality of mandrels, the midportion being between a first end and a second end of each mandrel;

inserting the plurality of mandrels into a plurality of cell members of the first bulk composite core and a plurality of cell members of the second composite core, thereby aligning the cell members of the first bulk composite core to the cell members of the second bulk composite core;

pressing the respective surface networks of the first bulk composite core and the second bulk composite core together; and

curing the adhesive.

9. The method according to claim **8**, wherein the step of curing the adhesive includes thermally expanding the plurality of mandrels.

10. The method according to claim **9**, wherein thermally expanding the plurality of mandrels applies pressure to the adhesive at an interior surface of the plurality of cell members of the first bulk composite core and an interior surface of the plurality of cell members of the second bulk composite core.

11. The method according to claim **8**, further comprising the step of:

removing the plurality of mandrels.

12. The method according to claim **8**, wherein the step of applying an adhesive to a midportion of each of a plurality of mandrels includes wrapping a film adhesive around an outer surface of each mandrel.

13. The method according to claim **8**, wherein the step of applying an adhesive to a midportion of each of a plurality of mandrels includes applying a paste adhesive around an outer surface of each mandrel.

14. A method processing a first bulk composite core and a second bulk composite core, the method comprising the steps of:

applying an adhesive to a first surface network of the first bulk composite core, the first surface network being an exposed surface at a first termination end of a plurality of cell members of the first bulk composite core;

inserting a plurality of mandrels into the plurality of cell members of the first bulk composite core and a plurality of cell members of the second bulk composite core, thereby aligning the cell members of the first bulk composite core to the cell members of the second bulk composite core, the second bulk composite core having a second surface network that is an exposed surface at a first termination end of a plurality of cell members of the second bulk composite core;

pressing together the first surface network of the first bulk composite core and the second surface network of the second bulk composite core together with the adhesive located therebetween;

curing the adhesive;

removing the plurality of mandrels; and

cutting through at least one of the first bulk composite core and the second bulk composite core so as to create a wafer therefrom.

15. The method according to claim **14**, further comprising: stabilizing at least one of the first bulk composite core and the second bulk composite core with a fixture.

16. The method according to claim **15**, the step of stabilizing at least one of the first bulk composite core and the second bulk composite core with a fixture comprises:

17

supporting at least one of the first bulk composite core and the second bulk composite core with an outer fixture having an inner surface that lies adjacent to outwardly exposed cell walls of outwardly located tube members of at least one of the first bulk composite core and the second bulk composite core. 5

17. The method according to claim 14, wherein the step of cutting through each of the tube members at least one of the first bulk composite core and the second bulk composite core so as to create a wafer therefrom includes cutting along a plane that is parallel to an exposed surface network of the either the first bulk composite core or the second bulk composite core. 10
